## 1 Basics

### Definitions

- A graph  $G$  is *non-trivial* if it contains at least one edge, equivalently if  $G$  is not an empty graph
- The *order* of  $G$  written  $|G|$ , is the number of vertices of  $G$ , i.e.  $|G| = |V|$
- The *size* of  $G$  written  $\|G\|$ , is the number of edges of  $G$ , i. e.  $\|G\| = |E|$ , if order of  $G$  is  $n$  then the size of  $G$  is between 0 and  $\binom{n}{2}$
- $N(S)$  the *neighbourhood* of  $S \subseteq V$  is the set of vertices in  $V$ . that have and adjacent vertex in  $S$ . Instead of  $N(\{v\})$  for  $v \in V$  we write  $N(v)$
- vertex of degree 1 is called *leaf*
- vertex of degree 0 is called *isolated vertex*
- *minimum degree* of  $G$ , denoted by  $\delta(G)$  is the smallest vertex degree in  $G$
- *maximum degree* of  $G$ , denoted by  $\Delta(G)$  is the highest vertex degree in  $G$
- graph  $G$  is called *k-regular*, with  $k \in \mathbb{N}$ , if all vertices have degree  $k$ .
- *average degree* of  $G$  is defined as  $d(G) = \frac{\sum_{v \in V} \deg(v)}{|V|}$   
We have

$$\delta(G) \leq d(G) \leq \Delta(G)$$

with equality if and only if  $G$  is  $k$ -regular

**Handshake Lemma** For ever graph  $G = (V, E)$  we have

$$2|E| = \sum_{v \in V} d(v)$$

*Proof.* By double counting the set  $X = \{(e, x) : e \in E(G), x \in V(G), x \in e\}$  then

$$|X| = \sum_{v \in V(G)} d(v)$$

and

$$|X| = \sum_{e \in E(G)} 2 = 2|E(G)|$$

by the principle of double counting the terms are equal. □

**Corollary** From this follows that the sum of all vertex degrees is even and therefore the number of vertices with odd degree is even.

**Proposition 3** If a graph  $G$  has minimum degree  $\delta(G) \geq 2$ , then  $G$  has a path of length  $\delta(G)$  and a cycle with at least  $\delta(G) + 1$  vertices.

*Proof.* Let  $P = (x_0, \dots, x_k)$  be a longest path in  $G$ . Then  $N(x_0) \subseteq V(P)$ , otherwise for  $x \in N(x_0) \setminus V(P)$  the path  $(x, x_0, x_1, \dots, x_k)$  would be a longer path.

Let  $i$  be the largest index such that  $x_i \in N(x_0)$ , then  $i \geq |N(x_0)| \geq \delta$ . So  $(x_0, x_1, \dots, x_i, x_0)$  is a cycle of length at least  $\delta(G) + 1$ .  $\square$

**Proposition 4** If for distinct vertices  $u$  and  $v$  a graph has a  $u$ - $v$ -walk, then it has a  $u$ - $v$ -path.

*Proof.* Consider a  $u$ - $v$ -walk  $W$  with the smallest number of edges. Assume that  $W$  does not form a path, then there is a repeated vertex,  $w$ , i.e.

$$W = u, e, v_1, e_1, \dots, e_k, w, e_{k+1}, \dots, e_l, w, e_{l+1}, \dots, v$$

Then  $W_1 = u, e, v_1, \dots, e_k, w, e_{k+1}, \dots, v$  is a shorter  $u$ - $v$ -walk, a contradiction.  $\square$

**Proposition 5** If a graph has a closed walk of odd length, then it contains an odd cycle.

*Proof.* Let  $W$  be the shortest closed odd walk. If  $W$  is a cycle the Proposition holds. Otherwise there is a repeated vertex, so  $W$  is an edge-disjoint union of two closed walks. The sum of the lengths of these walks is odd, therefore one of them is an odd closed walk shorter than  $W$  a contradiction to the minimality of  $W$ .  $\square$

**Proposition 6** If a graph has a closed walk with a non-repeated edge, then the graph contains a cycle.

*Proof.* Let  $W$  be a shortest walk with a non-repeated edge  $e$ . If  $W$  is a cycle, we are done. Otherwise, there is a repeated vertex and  $W$  is a union of two closed walks  $W_1$  and  $W_2$  that are shorter than  $W$ . One of them say  $W_1$ , contains  $e$ , a non-repeated edge. This contradicts the minimality of  $W$ .  $\square$

**Definition bipartite** A graph  $G = (V, E)$  is called *bipartite* if there exists natural numbers  $m, n$  such that  $G$  is isomorphic to a subgraph of  $K_{m,n}$ . Then the vertex set can be written as  $V = A \cup B$  such that  $E \subseteq \{ab : a \in A, b \in B\}$ . The sets  $A$  and  $B$  are called the *partite sets* of  $G$

**Proposition 1.5** A graph is bipartite if and only if it has no cycles of odd length.

*Proof.* skript

“ $\Rightarrow$ ”

Assume that  $G$  is a bipartite graph with parts  $A$  and  $B$ . Then any cycle has a form  $a_1, b_1, a_2, b_2, \dots, a_k, b_k, a_1$  where  $a_i \in A, b_i \in B, i \in [k]$ . Thus every cycle has even length.

“ $\Leftarrow$ ”

Assume  $G$  does not have cycles of odd length. We can assume that  $G$  is

connected, otherwise we can treat the connected components separately. Let  $v \in V(G)$ . Let  $A = \{u \in V(G) : \text{dist}(u, v) \equiv 0 \pmod{2}\}$  and let  $B = \{u \in V(G) : \text{dist}(u, v) \equiv 1 \pmod{2}\}$ . We claim that  $G$  is bipartite with parts  $A$  and  $B$ . To verify this it is sufficient to prove that  $A$  and  $B$  are independent sets. Let  $u_1 u_2 \in E(G)$  and let  $P_1$  be a shortest  $u_1$ - $v$ -path and  $P_2$  a shortest  $u_2$ - $v$ -path. Then the union of  $P_1, P_2$  and  $u_1 u_2$  forms a closed walk  $W$ . If  $u_1, u_2 \in A$  or  $u_1, u_2 \in B$  then  $W$  is a closed odd walk, because  $\text{dist}(v, u_1)$  and  $\text{dist}(v, u_2)$  are both even or odd. Thus by Prop. 5  $G$  contains an odd cycle, a contradiction. Thus for any edge  $u_1 u_2$  the adjacent vertices  $u_1$  and  $u_2$  are in different parts  $A$  or  $B$ . Therefore  $A$  and  $B$  are independent sets.  $\square$

*Proof.* Diestel

“ $\Leftarrow$ ”

Let  $T$  be a spanning tree in  $G$ , pick a root  $r \in T$  and denote the associated tree-order on  $V$  by  $\leq_T$  (this order expressing height if  $x < y$  then  $x$  lies *below*  $y$  in  $T$ ). For each  $v \in V(G)$  the unique path  $r$ - $v$ - $T$  has odd or even length. This defines a bipartition of  $V(G)$ , we show that  $G$  is bipartite with this partition. Let  $e = xy$  be an edge of  $G$ . If  $e \in T$  with  $x <_T y$  say, then  $r$ - $y$ - $T = r$ - $xy$ - $T$  and so  $x$  and  $y$  lie in different partition classes. If  $e \notin T$  then  $C_e := x$ - $y$ - $T$  +  $e$  is a cycle, and by the case treated already the vertices along  $x$ - $y$ - $T$  alternate between the two classes. Since  $C_e$  is even by assumption,  $x$  and  $y$  again lie in different classes.  $\square$

**Euler tour** A closed walk that traverses every edge of the graph exactly once is called an *Euler tour*.

**Theorem 1.6 (Eulerian Tour Condition)** A connected graph has an Eulerian Tour if and only if every vertex has even degree.

*Proof.* “ $\Rightarrow$ ”

The degree condition is necessary for an euler tour, because a vertex appearing  $k$  times in an Euler tour (or  $k + 1$  times if it is the starting and finishing vertex) must have degree  $2k$ .

“ $\Leftarrow$ ”

Show by induction on  $\|G\|$  that every connected Graph  $G$  with all degrees even has an Euler tour.  $\|G\| = 0$  is trivial.

Now let  $\|G\| \geq 1$ , since all degrees are even, we can find in  $G$  a non-trivial closed walk that contains no edge more than once. To find this walk we consider  $W$  a walk of maximal length and write  $F$  for the set of its edges. If  $F = E(G)$ , then  $W$  is an Euler tour.

Suppose, therefore  $G' := G - F$  has an edge.

For every vertex  $v \in G$ , an even number of edges of  $G$  at  $v$  lies in  $F$ , so the degrees of  $G'$  are again all even. Since  $G$  is connected,  $G'$  has an edge  $e$  incident with a vertex on  $W$ . By I.H. the component  $C$  of  $G'$  containing  $e$  has an Euler tour. Concatenating this with  $W$  (suitably re-indexed), we obtain a closed walk in  $G$  that contradicts the maximal length of  $W$ .  $\square$

## Definitions

- graph  $G$  is *connected* if any two vertices are linked by a path.
- a maximal connected subgraph of  $G$  is called a *connected component* of  $G$ .
- acyclic graphs are called *forests*
- a graph  $G$  is called a *tree* if  $G$  is connected and acyclic.

**Lemma 7** Every tree on at least two vertices has a leaf.

*Proof.* If a tree  $T$  on at least two vertices does not have leaves then every vertex has degree  $>$  than 2, so we have a cycle in  $T$  with length  $\geq 3$ , a contradiction.  $\square$

**Lemma 8** A tree of order  $n \geq 1$  has exactly  $n - 1$  edges.

*Proof.* We prove the statement by induction on  $n$ . When  $n = 1$ , there are no edges.

**I.H.:** Assume that each tree on  $n = k$  vertices has  $k - 1$  edges, with  $k \geq 1$ .

**Step:** Lets prove that each tree on  $k + 1$  vertices has  $k$  edges. Consider a tree  $T$  on  $k + 1$  vertices. Since  $k + 1 \geq 2$ ,  $T$  has a leaf  $v$ . Let  $T' = T - \{v\}$ . We see that  $T'$  is connected because any  $u$ - $w$ -path in  $T$ , for  $u \neq v$  and  $w \neq v$ , does not contain  $v$ . We see also that  $T'$  is acyclic, because deleting vertices from an acyclic graph does not create new cycles. Thus  $T'$  is a tree on  $k$  vertices. By I.H.  $|E(T')| = k - 1$ . Thus  $|E(T)| = |E(T')| + 1 = (k - 1) + 1 = k$ .  $\square$

**Lemma 9** Every connected graph contains a spanning tree.

*Proof.* Let  $G$  be a connected graph. Consider  $T$ , an acyclic spanning subgraph of  $G$  with largest number of edges. If it is a tree we are done.

Otherwise,  $T$  has more than one component. Consider vertices  $u$  and  $v$  from different components of  $G$ . Consider a shortest  $u$ - $v$ -path  $P$  in  $G$ . Then  $P$  has an edge  $e = xy$  with exactly one vertex  $x$  in one of the components of  $T$ . Then  $P$  has an edge  $e = xy$  with exactly one vertex  $x$  in one of the components of  $T$ . Then  $T \cup \{e\}$  is acyclic.  $\square$

**Lemma 10** A connected graph on  $n \geq 1$  vertices and  $n - 1$  edges is tree.

*Proof.* TODO skript  $\square$

**Lemma 11** The vertices of every connected graph on  $n \geq 2$  vertices can be ordered  $(v_1, \dots, v_n)$  so that for every  $i \in \{1, \dots, n\}$  the Graph  $G[\{v_1, \dots, v_i\}]$  is connected.

*Proof.* TODO skript  $\square$

**Tree equivalences** For any graph  $G = (V, E)$  the following are equivalent:

- (i)  $G$  is a tree, i.e.  $G$  is connected and acyclic.
- (ii)  $G$  is connected, but for any  $e \in E$  the graph  $G - e$  is not connected (minimally connected)
- (iii)  $G$  is acyclic, but for any  $x, y \in V(G), xy \notin E(G)$  the graph  $G + xy$  has a cycle. (maximally acyclic)
- (iv)  $G$  is connected and 1-degenerate
- (v)  $G$  is connected and  $|E| = |V| - 1$
- (vi)  $G$  is acyclic and  $|E| = |V| - 1$
- (vii)  $G$  is connected and every non-trivial subgraph of  $G$  has a vertex of degree at most 1.
- (viii) Any two vertices are joined by a unique path in  $G$ .

*Proof.*

□

**Definition Contract** For an edge  $e = xy$  in  $G$  we define  $G \circ e$  as the graph obtained from  $G$  by identifying  $x$  and  $y$  and removing (if necessary) loops and multiple edges. We say that  $G \circ e$  arises from  $G$  by *contracting the edge*  $e$ .

**Definition Complement** The *complement* of  $G$ , denoted by  $\overline{G}$  is defined as the graph  $(V, \binom{V}{2} \setminus E)$ . In particular  $G + \overline{G}$  is a complete graph and  $\overline{G} = (G + \overline{G}) - E$ .

## 2 Important Graphs

**Complete Graph, Clique:**

the *complete graph*  $K_n$  on  $n$  vertices is isomorphic to  $([n], \binom{[n]}{2})$

**Cycle**

$C_n$  on  $n$  vertices with  $n \geq 3$  is isomorphic to  $([n], \{\{i, i+1\} : i = 1, \dots, n-1\} \cup \{n, 1\}\})$ , the *length of a cycle* is its number of edges.

**Empty Graph**

$E_n$  on  $n$  vertices is isomorphic to  $([n], \emptyset)$ .

Empty graphs correspond to *independent sets*.

**Complete Bipartite Graph**

$K_{m,n}$  on  $n+m$  vertices is isomorphic to  $(A \cup B, \{xy : x \in A, y \in B\})$  where  $|A| = m$  and  $|B| = n$  and  $A \cap B = \emptyset$ .

**Complete r-partite graph** with  $r \geq 2$  is isomorphic to

$$(A_1 \cup \dots \cup A_r, \{xy : x \in A_i, y \in A_j, i \neq j\})$$

where  $A_1, \dots, A_r$  are disjoint non-empty finite sets.
